RequestDispatcher.forward and include .......................................................... 77
Request.getInputStream and getReader ............................................................ 78

Index .................................................................................................................. 79

This book has the following chapters and appendices:

- Chapter 1, “Using Servlets and JavaServer Pages.”
  This chapter discusses how to enable and install servlets and JSPs in iPlanet Web Server 4.1. It explains how to specify settings for servlets and for the JRE and JDK by using the Server Manager interface or by editing configuration files.

- Chapter 2, “Servlet and JSP Examples.”
  This chapter discusses example servlets and JSP.

- Appendix A, “Session Managers.”
  This appendix discusses the session managers provided with iPlanet Web Server and gives an overview of a sample session manager that you can extend to customize session behavior to suit your own needs.

- Appendix B, “Servlet Settings in obj.conf.”
  This appendix discusses how the configuration file obj.conf changes depending on the settings for servlets and JSP.

- Appendix C, “Properties Files.”
  This appendix discusses the servlets.properties file, which contains configuration information for servlets, the rules.properties file, which defines virtual paths for servlets, and the contexts.properties file, which defines contexts for servlets.

- Appendix D, “JVM Configuration.”
  This appendix discusses how to manually specify JVM configuration information.

- Appendix E, “Debugging Servlets and JSPs.”
  This appendix discusses how to debug servlets and JSPs.
• Appendix F, “Remote Servlet Profiling.”
   This appendix discusses how to enable remote profiling for servlets.

• Appendix G, “API Clarifications.”
   This chapter discusses methods in the Servlets API that behave marginally
differently in iPlanet Web Server than specified in the Sun Microsystems’
Servlets API documentation or where the behavior documented by Sun
Microsystems is ambiguous.

Note  Throughout this manual, all Unix-specific descriptions apply to the Linux
operating system as well, except where Linux is specifically mentioned.
iPlanet Web Server 4.1 supports servlets and JavaServer Pages (JSP). This chapter gives a brief overview of servlets and JSPs and discusses how to enable and configure them in iPlanet Web Server 4.1.

The sections in this chapter are:
- Servlets
- JavaServer Pages
- What Does the Server Need to Run Servlets and JSP?
- Serving Servlets and JSP
- Using the Server Manager Interface
- Activating Servlets and JSP
- Configuring Global Servlet Attributes
- Registering Servlet Directories
- Registering Individual Servlets
- Specifying Servlet Virtual Paths
- Specifying Servlet Contexts
- Configuring JRE/JDK Paths
- Deleting Version Files
- Configuring JVM
- Running 0.92 JSP
- Maximizing Servlet Performance
Java servlets are server-side Java programs that web servers can run to generate content in response to a client request in much the same way as CGI programs do. Servlets can be thought of as applets that run on the server side without a user interface. Servlets are invoked through URL invocation.

iPlanet Web Server 4.1 includes support for JavaSoft's Servlet API at the level of the 2.2.1 specification.

**Note** Servlet API version 2.2.1 is fully backward compatible with version 2.1, so all existing servlets will continue to work without modification or recompilation.

To develop servlets, use Sun Microsystems' Java Servlet API. For information about using the Java Servlet API, see the documentation provided by Sun Microsystems at:

iPlanet Web Server 4.1 includes all the files necessary for developing Java Servlets. The `servlets.jar` file is in the iPlanet Web Server 4.1 installation directory at:

`server_root/bin/https/jar`

When compiling servlets, make sure the `servlets.jar` file is accessible to your Java compiler. Include the `servlets.jar` file in your CLASSPATH.

iPlanet Web Server 4.1 supports the `<SERVLET>` tag as introduced by Java Web Server. This tag allows you to embed servlet output in an HTML file. No configuration changes are necessary to enable this behavior. If SSI and servlets are both enabled, the `<SERVLET>` tag is enabled.

The `<SERVLET>` tag syntax is slightly different from that of other SSI commands; it resembles the `<APPLET>` tag syntax:

```html
<servlet name=name code=classfile codebase=path iParam1=v1 iParam2=v2>
  <param name=param1 value=v3>
  <param name=param2 value=v4>
  ...
  ...
</servlet>
```
The code parameter, which specifies the .class file for the servlet, is always required. The .class extension is optional. The codebase parameter is required if the servlet is not defined in the servlets.properties file and the .class file is not in the same directory as the HTML file containing the <SERVLET> tag. The name parameter is required if the servlet is defined in the servlets.properties file, and must match the servlet name defined in that file.

For more information about the servlets.properties file, see Appendix C, “Properties Files.” For more information about SSI commands, see the Programmer’s Guide for iPlanet Web Server.

iPlanet Web Server 4.1 supports JavaServer Pages (JSP) to the level of JSP API 1.1 compliance.

Note

JSP API version 1.x is not backward compatible with JSP API version 0.92. To run version 0.92 JSPs, you must create legacy directories for them as described in the section “Running 0.92 JSP” on page 27.

A JSP is a page, much like an HTML page, that can be viewed in a web browser. However, as well as containing HTML tags, it can include a set of JSP tags that extend the ability of the web page designer to incorporate dynamic content in a page. These tags provide functionality such as displaying property values and using simple conditionals.

One of the main benefits of JSPs is that, like HTML pages, they do not need to be compiled. The web page designer simply writes a page that uses HTML and JSP tags and puts it on their web server. The web page designer does not need to learn how to define Java classes or use Java compilers.

JSP pages can access full Java functionality in the following ways:

• by embedding Java code directly in scriptlets in the page
• by accessing Java beans
• by using server-side tags that include Java servlets

Both beans and servlets are Java classes that need to be compiled, but they can be defined and compiled by a Java programmer, who then publishes the interface to the bean or the servlet. The web page designer can access a pre-compiled bean or servlet from a JSP page.
What Does the Server Need to Run Servlets and JSP?

For information about creating JSPs, see Sun Microsystem's JavaServer Pages web site at:

For information about Java Beans, see Sun Microsystem's JavaBeans web page at:

http://java.sun.com/beans/index.html

What Does the Server Need to Run Servlets and JSP?

iPlanet Web Server 4.1 includes the Java Runtime Environment (JRE) but not the Java Development Kit (JDK) due to licensing restrictions. The server can run servlets using the JRE, but it needs the JDK to run JSP.

iPlanet Web Server 4.1 requires you to use the following recommended versions of JRE/JDK or later versions, with different platforms requiring different versions, as summarized in Table 1.1.

Table 1.1 Supported JRE/JDK Versions by Platform

<table>
<thead>
<tr>
<th>Platform</th>
<th>JRE/JDK Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Solaris Sparc</td>
<td>1.2.2_01</td>
</tr>
<tr>
<td>Windows NT</td>
<td>1.2.2_01</td>
</tr>
<tr>
<td>HPUX</td>
<td>1.2.2_02</td>
</tr>
<tr>
<td>AIX</td>
<td>1.2.1</td>
</tr>
<tr>
<td>DEC</td>
<td>1.2.1-2</td>
</tr>
<tr>
<td>Linux</td>
<td>1.2.2RC3+</td>
</tr>
<tr>
<td>IRIX</td>
<td>1.2.1</td>
</tr>
</tbody>
</table>

Check the iPlanet Web Server Installation and Migration Guide and the latest release notes for updates on required JDK versions.
Serving Servlets and JSP

On Sun Solaris, the JRE included is the JRE 1.2.2 reference implementation from JavaSoft. For better performance, use the latest SunSoft production release of JDK.

JDK 1.2 (and other JDK versions) are available from Sun Microsystems at:
http://java.sun.com/products/jdk/1.2/

You can specify the path to the JDK in either of the following ways:

• You can specify the path during the server installation process.
  When you install iPlanet Web Server 4.1, one of the dialog boxes in the installation process asks if you want to use a custom Java Development Kit (JDK), and if so, you can specify the path to it.

• You can specify it after the server is installed.
  To specify the path to the JDK, switch to the Web Server Administration Server, select the Global Settings tab, and use the Configure JRE/JDK Paths page, as discussed in the section “Configuring JRE/JDK Paths” on page 22.

Whether you specify the path to the JDK during installation or later, the path is the directory in which you installed the JDK.

Serving Servlets and JSP

iPlanet Web Server 4.1 includes an appropriate version of the Java runtime environment (JRE) for running servlets. For the server to be able to serve JSP, you must specify a path to a Java Development Kit (JDK) as discussed in the section “What Does the Server Need to Run Servlets and JSP?” on page 12.

For the server to serve servlets and JSP, servlet activation must be enabled. (See the section “Activating Servlets and JSP” on page 15 for details.)

When servlets are enabled, you have a choice of two ways to make a servlet accessible to clients:

• Put the servlet class file in one of the directories that has been registered with the iPlanet Web Server as a servlet directory. For more information, see “Registering Servlet Directories” on page 16.
Define a servlet virtual path for the servlet. In this case, the servlet class can be located anywhere in the file system or even reside on a remote machine. For more information, see “Specifying Servlet Virtual Paths” on page 19.

No special steps are needed to enable JSP pages other than making sure that JSP is enabled on the iPlanet Web Server. So long as JSP is enabled, the iPlanet Web Server treats all files with a .jsp extension as JSPs. (Do not put JSP files in a registered servlet directory, since the iPlanet Web Server expects all files in a registered servlet directory to be servlets.) An exception is a JSP page written to the 0.92 spec, which must be placed in a legacy directory; see the section “Running 0.92 JSP” on page 27 for details.

In detail, to enable the iPlanet Web Server to serve servlets and JSP pages, do the following steps:

1. Activating Servlets and JSP (this is the only step needed to enable JSP)
2. Configuring Global Servlet Attributes
3. Registering Servlet Directories
4. Registering Individual Servlets if Needed
5. Specifying Servlet Virtual Paths if Desired
6. Configuring JVM if Necessary

---

Using the Server Manager Interface

For information about using the Server Manager interface to specify settings for servlets, see the following topics in the online help. All these pages are located on the Servlets tab.

- The Enable/Disable Servlets/JSP Page
- The Servlet Directory Page
- The Legacy JSP Directory Page
- The Configure Global Servlet Attributes Page
- The Configure Servlet Attributes Page
- The Configure Servlet Virtual Path Translation Page
- The Configure JVM Attributes Page
- The Delete Version Files Page
In addition, the Configure JRE/JDK Paths page on the Global Settings tab in the Web Server Administration Server allows you to specify paths to the JRE and JDK.

**Activating Servlets and JSP**

To enable and disable servlets and JSP in iPlanet Web Server 4.1, use the Servlets>Enable/Disable Servlets/JSP page in the Server Manager interface.

You must enable both servlets and JSP to run JSP. Even if servlets are enabled, JSP can still be disabled. However, if you disable servlets, JSP is automatically also disabled. In this case, if you enable servlets later, you will need to re-enable JSP also if desired.

You can also define a thread pool to be used for servlets. For more information about thread pools, see “Maximizing Servlet Performance” on page 27 and “Adding and Using Thread Pools” in Chapter 7, “Configuring Server Preferences,” in the iPlanet Web Server Administrator’s Guide.

To enable servlets programmatically, add the following lines to obj.conf. These directives first load the shared library containing the servlet engine, which is in `server_root/bin/https/bin/NSServletPlugin.dll` on Windows NT or `server_root/bin/https/lib/libNSServletPlugin.so` on Unix. Then they initialize the servlet engine.

```ini
Init fn="load-modules" shlib="server_root/bin/https/bin/NSServletPlugin.dll"
funcs="NSServletEarlyInit,NSServletLateInit,NSServletNameTrans,NSServletService"
shlib_flags="(global|now)"
Init fn="NSServletEarlyInit" EarlyInit="yes"
Init fn="NSServletLateInit" LateInit="yes"
```

In the default object in obj.conf, add the following NameTrans directive:

```ini
NameTrans fn="NSServletNameTrans" name="servlet"
```

By default, regardless of whether servlets are enabled or disabled, the file obj.conf contains additional objects with names such as servlet, jsp, and ServletByExt. Do not delete these objects. If you delete them, you can no longer activate servlets through the Server Manager.

A JSP page written to the 0.92 spec must be placed in a legacy directory; see the section “Running 0.92 JSP” on page 27 for details.
Configuring Global Servlet Attributes

You can specify the following optional servlet attributes:

- **Startup Servlets** -- servlets to be loaded when the iPlanet Web Server starts up.
- **Session Manager** -- the session manager for servlets. For more information about the session manager, see Appendix A, “Session Managers.”
- **Session Manager Args** -- the session manager arguments for the servlet engine. For more information about the session manager, see Appendix A, “Session Managers.”
- **Reload Interval** -- the time period that the server waits before re-loading servlets and JSPs if they have changed on the server. The default value is 5 seconds.

You can set these attributes interactively in the Servlets>Configure Global Servlet Attributes page in the Server Manager interface. Alternatively, you can edit the configuration file `servlets.properties` in the server's `config` directory.

The following code shows an example of the settings in `servlets.properties`:

```properties
# General properties:
servlets.startup=hello
servlets.config.reloadInterval=5
servlets.config.docRoot=C:/Netscape/Server4/docs
servlets.sessionmgr=com.netscape.server.http.session.SimpleSessionManager
```

Registering Servlet Directories

One of the ways to make a servlet accessible to clients is to put it into a directory that is registered with the iPlanet Web Server as a servlet directory. Servlets in registered servlet directories are dynamically loaded when needed. The server monitors the servlet files and automatically reloads them on the fly as they change.

You can register any number of servlet directories for the iPlanet Web Server. Initially, the iPlanet Web Server has a single servlet directory, which is `server_root/docs/servlet/`.
Registering Servlet Directories

For example, if the SimpleServlet.class servlet is in the servlet subdirectory of the server's document root directory (the default servlet directory), you can invoke the servlet by pointing the web browser to:

http://your_server/servlet/SimpleServlet

The iPlanet Web Server expects all files in a registered servlet directory to be servlets. The server treats any files in that directory that have the .class extension as servlets. The iPlanet Web Server does not correctly serve other files, such as HTML files or JSPs, that reside in that directory.

The server can have multiple servlet directories. You can map servlet directories to virtual directories if desired. For example, you could specify that http://poppy.my_domain.com/products/ invokes servlets in the directory server_root/docs/january/products/servlets/.

To register servlet directories and to specify their URL prefixes, use the Servlets>Servlet Directory page in the interface.

Alternatively, you can register servlet directories by adding appropriate NameTrans directives to the default object in the file obj.conf, such as:

NameTrans fn="pfx2dir" from="/products" dir="d:/netscape/server4/docs/january/products/servlets/* name="ServletByExt"

You can invoke a servlet in a subdirectory of a registered servlet directory if you include a package directive in the servlet code that corresponds to the path from the registered servlet directory. For example, suppose the servlet is in the following location, and that server_root/docs/servlet/ is a registered servlet directory:

server_root/docs/servlet/HelloWorld/HelloWorldServlet.class

Include the following package directive as the first line in the Java source file:

package HelloWorld;

You can then invoke the servlet by pointing the web browser to:

http://your_server/servlet/HelloWorld.HelloWorldServlet
Registering Individual Servlets

The iPlanet Web Server treats any file in a registered servlet directory as a servlet. There is no need to register individual servlets that reside in these directories unless any of the following criteria apply:

- The servlet takes input parameters that are not passed through the request URL.
- You want to set up additional virtual URLs for the servlet.
- Your servlets are packaged or in a .jar file. The server does not search .class or .jar files for packaged servlets.

If any of these conditions is true, register the individual servlet by using the Servlets>Configure Servlet Attributes page in the Server Manager interface. Alternatively, you can edit the file servlets.properties to add an entry for the servlet.

When registering an individual servlet, specify the following attributes:

- Servlet Name -- The iPlanet Web Server uses this value as a servlet identifier to internally identify the servlet. (This identifier is not part of the URL that is used to invoke the servlet, unless by coincidence the identifier is the same as the class code name.)

- Servlet Code (class name) -- the name of the class file. You do not need to specify the .class extension.

- Servlet Classpath -- This is the absolute pathname or URL to the directory or zip/jar file containing the servlet. The classpath can point anywhere in the file system. The servlet classpath may contain a directory, a .jar or .zip file, or a URL to a directory. (You cannot specify a URL as a classpath for a zip or jar file.)

If the servlet classpath is not a registered servlet directory, you must additionally provide a servlet virtual path for it (as discussed in “Specifying Servlet Virtual Paths” on page 19) to make the servlet accessible to clients.

iPlanet Web Server supports the specification of multiple directories, jars, zips, and URLs in the servlet classpath.

- Servlet Args -- a comma delimited list of additional arguments for the servlet if required.
For example, in Figure 1.1, the Servlets>Configure Servlet Attributes page of the Server Manager interface shows configuration information for a servlet whose class file buyNow1A resides in the directory D:/Netscape/server4/docs/servlet/buy. This servlet is configured under the name BuyNowServlet. It takes additional arguments of arg1=45, arg2=online, arg3="quick shopping".

Figure 1.1 Configuring attributes for an individual servlet

The following code shows an example of the configuration information for the same servlet in servlets.properties:

```java
servlet.BuyNowServlet.classpath=D:/Netscape/server4/docs/servlet/buy;D:/Netscape/server4/docs/myclasses
servlet.BuyNowServlet.code=BuyNow1A
servlet.BuyNowServlet.initArgs=arg1=45, arg2=online, arg3="quick shopping"
```

Note that you can specify multiple values as the servlet classpath if needed.

### Specifying Servlet Virtual Paths

If you register a servlet individually instead of putting it in a servlet directory, you must define a servlet virtual path for it. For example, you could specify that the URL

http://poppy.my_domain.com/plans/plan1

invokes the servlet defined in the directory

`server_root/docs/plans/releaseA/planP2Version1A.class`
You can set up servlet virtual paths for servlets that reside anywhere in the file system, in or out of a registered servlet directory.

To specify a servlet virtual path, use the Servlets>Configure Servlet Virtual Path Translation page in the Server Manager interface. In this page, specify the virtual path name and the servlet name. You can alternatively manually edit the rules.properties configuration file to add a servlet virtual path. Only servlets for which a virtual path has been set up can use initial arguments (See “GenericServlet.getParameter and getParameterNames” on page 75 for information about initial arguments.)

Before using a servlet virtual path, a servlet identifier (or servlet name) must be added for the servlet in the Servlets>Configure Servlet Attributes page of the interface (or in the servlets.properties configuration file).

**Virtual Servlet Path Example**

This example shows how to specify that the logical URL

http://poppy.my_domain.com/plans/plan1

invokes the servlet defined in

server_root/docs/plans/releaseA/planP2Version1A.class.

1. **Specify the servlet identifier, class file, and class path.**

   In the Servlets>Configure Servlet Attributes page in the interface, do the following:

   - In the Servlet Name field, enter an identifier for the servlet, such as `plan1A`. (Notice that this is not necessarily the same as the class file name).
   - In the Servlet Code field, enter the name of the class file, which is `planP2Version1A`. Don't specify any directories. The .class extension is not required.
   - In the Servlet Classpath field, enter the absolute path name for the directory, jar or zip file where the servlet class file resides, or enter a URL for a directory. In this example, you would enter `server_root/docs/servlet/plans/releaseA`. (For example: D:/netscape/server4/docs/servlet/plans/releaseA.)
   - In the Servlet Args field, enter the additional arguments that the servlet needs, if any. (This example does not use extra arguments.)
Figure 1.2 shows the settings in the interface.

Save the changes.

Figure 1.2 Specifying the servlet name, code, and class path

To make this change programmatically, add the following lines to the configuration file `servlets.properties`:

```properties
servlet.plan1A.classpath=D:/Netscape/server4/docs/servlet/plans/releaseA/
servlet.plan1A.code=planP2Version1A
```

2. Specify the virtual path for the servlet.

In the Servlets>Configure Servlet Virtual Path Translations page, do the following:

- In the Virtual Path field, enter the virtual path name. Note that the server name is implied as a prefix, so in this case you would only need to enter `/plans/plan1` to specify the virtual path `http://poppy.mcom.com/plans/plan1`.

- In the Servlet field, enter the identifier for the servlet that is invoked by this virtual path. This is the servlet identifier that you specified in the Configure Servlet Attributes page, which in this case is `plan1A`.

Save the changes.
Specifying Servlet Contexts

Figure 1.3 shows the settings in the interface.

![Servlet Virtual Path Translation](image)

Figure 1.3 Adding a virtual path

To do this programmatically, add the following line to rules.properties:

`/plans/plan1=plan1A`

After this virtual servlet path has been established, if a client sends a request to the server for the URL `http://poppy.my_domain.com/plans/plan1`, the server sends back the results of invoking the servlet in `server_root/docs/servlet/plans/releaseA/plan2PVersion1A.class`.

**Specifying Servlet Contexts**

Contexts allow multiple servlets to exchange data and access each other’s fields. Contexts are useful for defining virtual servers or for code isolation. You define contexts in the `servlets.properties` and `contexts.properties` files. For more information, see Appendix C, “Properties Files.”

**Configuring JRE/JDK Paths**

When you install iPlanet Web Server 4.1, you can choose to install the Java Runtime Environment (JRE) that is shipped with the server, or you can specify a path to your own JRE or the Java Development Kit (JDK).
The server can run servlets using the JRE, but it needs the JDK to run JSP. The JDK is not bundled with the iPlanet Web Server, but you can download it for free from Sun Microsystems at:

http://java.sun.com/products/jdk/1.2/

iPlanet Web Server 4.1 requires you to use version of the JDK listed in the section "What Does the Server Need to Run Servlets and JSP?" on page 12.

Regardless of whether you choose to install the JRE or specify a path to the JDK during installation, you can tell the iPlanet Web Server to switch to using either the JRE or JDK at any time. Switch to the Web Server Administration Server, select the Global Settings tab, and use the Configure JRE/JDK Paths page. You can also change the path to the JDK in this page.

On the Configure JRE/JDK Paths page, supply values for the following fields if you select the JDK radio button:

- **JDK Path**
  Enter the path for the JDK. This is the directory where you installed the JDK.

- **JDK Runtime Libpath**
  Enter the runtime library path for the JDK.

- **JDK Runtime Classpath**
  The class path includes the paths to the directories and jar files needed to run the servlet engine, the servlet examples, and any other paths needed by servlets that you add. You can add new values to the existing class path, but don’t delete the existing value since it includes paths that are essential for servlet operation.

Supply values for the following fields if you select the JRE radio button:

- **JRE Path**
  Enter the path for the JRE. This is the directory where you installed the JRE.

- **JRE Runtime Libpath**
  Enter the runtime library path for the JRE.

**Note** If you are not sure of the JDK runtime libpath, the JDK runtime classpath, or the JRE runtime libpath, leave these fields blank to tell the server to use the default paths.
Deleting Version Files

It is easiest to use the Configure JRE/JDK Paths page to switch between the JRE and the JDK, but you can also make the change programmatically, as follows:

- **On Unix:**
  
  Edit the file `server_root/https-admserv/start-jvm`.

  If the server is currently using the JRE, this file has a variable `NSES_JRE`. To enable the server to use a JDK, add the variable `NSES_JDK` whose value is the JDK directory. You'll also need to change the value of the `NSES_JRE` variable.

  The `NSES_JDK` should point to the installation directory for the JDK, while the `NSES_JRE` should point to the JRE directory in the installation directory for JDK (that is, `jdk_dir/jre`).

- **On Windows NT:**

  Add the path to the Java libraries to the `extrapath` setting in `magnus.conf`.

  Edit the `NSES_JDK` and `NSES_JRE` variables in the registry `HKEY_LOCAL_MACHINE/SOFTWARE/Netscape/Enterprise/4.0/`. If the server is enabled to use the JDK, both these variables are needed. If the server is to use the JRE, only the `NSES_JRE` variable should be set.

  The `NSES_JDK` should point to the installation directory for the JDK, while the `NSES_JRE` should point to the JRE directory in the installation directory for JDK (that is, `jdk_dir/jre`).

**Note** To activate changes to the JRE/JDK paths, you must restart the server from the On/Off option on the Preferences tab.

### Deleting Version Files

The server uses two directories to cache information for JavaServer Pages (JSP) and servlets:

- **ClassCache**
  
  When the server serves a JSP page, it creates a `.java` and a `.class` file associated with the JSP and stores them in the JSP class cache under the `ClassCache` directory.

- **SessionData**
If the server uses the MMapSessionManager session manager, it stores persistent session information in the SessionData directory. (For more information about session managers, see Appendix A, “Session Managers.”)

Each cache has a version file containing a version number that the server uses to determine the structure of the directories and files in the caches. You can clean out the caches by simply deleting the version file.

When the server starts up, if it does not find the version files, it deletes the directory structures for the corresponding caches and re-creates the version files. Next time the server serves a JSP page, it recreates the JSP class cache. The next time the server serves a JSP page or servlet while using MMapSessionManager session manager, it recreates the session data cache.

If a future upgrade of the server uses a different format for the caches, the server will check the number in the version file and clean up the caches if the version number is not correct.

You can delete the version files simply by deleting them from the ClassCache or SessionData directories as you would normally delete a file, or you can use the Servlets>Delete Version Files page in the Server Manager to delete them. After deleting one or both version files, be sure to restart the iPlanet Web Server to force it to clean up the appropriate caches and to recreate the version files before the server serves any servlets or JSPs.

Configuring JVM

If necessary, you can configure parameters for JVM either by using the Servlets>Configure JVM Attributes page in the Server Manager interface, or by editing jvm12.conf.

The default settings in iPlanet Web Server for JVM are suitable for running servlets. However, there may be times when you want to change the settings. For example, if a servlet or bean file uses a JAR file, add the JAR location to the Classpath variable. To enable the use of a remote profiler, set the OPTITTDIR and Profiler variables.

Note: A few attributes on the Configure JVM Attributes page on the Servlets tab show as “Default.” Since you can use different JVMs, these default values are unknown. You cannot query a JVM to find out the actual default values; instead, refer to your JVM documentation. For example, for Sun’s JVM, if you
choose Yes for the JIT Compiler option, it shows as “Default” because JIT is enabled in the JVM by default. However, if you choose No for the JIT compiler, an explicit entry, `jvm.compiler=NONE`, is added to the `jvm12.conf` file.

The JVM parameters you can set are:

- **Option** -- You can set any options allowed by the vendor's JVM.
- **Profiler** -- If you are using the Optimizeit! 3.0 profiler from Intuitive Systems, enter the value `optimizeit`. For more information about this optimizer, see Appendix F, “Remote Servlet Profiling.”

- **OPTITDIR** -- If you are using the Optimizeit! 3.0 profiler from Intuitive Systems, enter the pathname for the directory where Optimizeit! resides, for example, `D:/App/IntuitiveSystems/OptimizeIt30D`. For more information about this optimizer, see Appendix F, “Remote Servlet Profiling.”

- **Minimum Heap Size** -- determines the minimum heap size allocated for Java.

- **Maximum Heap Size** -- determines the maximum heap size allocated to Java.

- **Compiler** -- You can specify options to turn on and off JIT (just-in-time compiler). See your JVM documentation for details.

- **Classpath** -- Enter additional classpath values as needed. For example, if a JSP uses a bean that is packaged in a JAR, add the JAR path to the classpath. The classpath must not include backslashes in directory names. If you use backslashes in the directory path when using the Web Server Administrative Server interface, the system automatically converts the backslashes to forward slashes. However, if you edit the `jvm12.conf` file, do not use backslashes in directory names.

- **Enable Class GC** -- Specifies whether or not to enable class garbage collection. The default is yes.

- **Verbose Mode** -- Determines whether the JVM logs a commentary on what it is doing, such as loading classes. The commentary appears in the error log.

- **Enable Debug** -- You can enable or disable remote debugging. The default is disabled. For more information about remote debugging, see Appendix E, “Debugging Servlets and JSPs.”
Running 0.92 JSP

JSP API version 1.x is not backward compatible with version 0.92. However, the iPlanet Web Server correctly serves JSPs written to the 0.92 spec if you place them in JSP legacy directories. If a 0.92 JSP does not reside in a JSP legacy directory, it will not work.

The Legacy JSP Directory page in the Servlets tab of the Server Manager allows you to add legacy JSP directories. For information about how to use this page, see the Legacy JSP Directory page in the online help.

JSP legacy directories can contain JSPs and other files such as HTML pages.

Maximizing Servlet Performance

Consider the following guidelines for improving servlet performance:

• Use Sun’s JVM on Solaris—it’s up to 50% faster than JavaSoft’s.

• If you edit your obj.conf file manually, make sure that the servlet NameTrans (NameTrans fn="NSServletNameTrans" name="servlet") is always the first NameTrans directive.

  This directive uses a highly optimized URI cache for loaded servlets and returns REQ_PROCEED if the match is found, thus eliminating the need of other NameTrans directives to be executed.

• Servlets defined individually (via the Configure Servlet Attributes page or rules.properties and servlets.properties) are slightly faster than dynamically loaded servlets (in servlet directories).

• The jvm12.conf file has a configuration parameter, jvm.stickyAttach.

  Setting the value of this parameter to 1 causes threads to remember that they are attached to the JVM, thus speeding up request processing by eliminating AttachCurrentThread and DetachCurrentThread calls. It can, however, have a side-effect: recycled threads which may be doing other processing can be suspended by the garbage collector arbitrarily.
Thread pools can be used to eliminate this side effect for other subsystems. For more information about thread pools, see “Adding and Using Thread Pools” in Chapter 7, “Configuring Server Preferences,” in the iPlanet Web Server Administrator's Guide.

- Increase the front-end thread stack size in magnus.conf (via the StackSize variable), or the respective pool stack size parameter if you’re using thread pools. For more information, see the NSAPI Programmer’s Guide for iPlanet Web Server.

- Increase the heap size to help garbage collection: jvm.minHeapSize or maxHeapSize or the Configure JVM Attributes page.

- Ensure that your classpath is short: jvm.classpath (if you don't need some of the examples). You can set jvm.include.CLASSPATH=1, so it won’t inherit the CLASSPATH environment variable.

- Sometimes, iPlanet Web Server 4.1 may run out of stack space if applications use deep recursion when a JIT compiler is enabled, especially on UNIX platforms where the default stack size is small, or in any cases where very complex JSP pages are used.

  You can set the stack space using the StackSize parameter in the magnus.conf file. For more information, see the NSAPI Programmer’s Guide for iPlanet Web Server.

- The use of the NSAPI cache improves servlet performance in cases where the obj.conf configuration file has many directives. To enable the NSAPI cache, include the following line in obj.conf:

  \[Init fn="nsapi-cache-init" enable=true\]

- The session ID generator, which is used for servlet sessions, employs cryptographically strong unique random number generation algorithms. This may present a performance problem on older, slow machines. For more information, see Appendix A, "Session Managers."
This chapter discusses some Servlet and JSP examples. It has the following sections:

- Examples Shipped with iPlanet Web Server 4.1
- Servlet Examples
- JSP Examples

Examples Shipped with iPlanet Web Server 4.1

iPlanet Web Server 4.1 comes with a set of example servlets and JSP files. You can find them at the following location:

```
server_root/plugins/samples/servlets
```

This directory contains the following directories:

- beans -- Contains example Java Bean files for JSP 0.92.
- beans.10 -- Contains example Java Bean files for JSP 1.x.
- bookstore -- Contains files for an online bookstore example. This example contains both servlets and JSPs.
Servlet Examples

• jsp.092 -- Contains subdirectories that each contain an example for JSP 0.92. To use one of these examples, you must place it in a legacy directory; see “Running 0.92 JSP” on page 27 for details.

• jsp.10 -- Contains subdirectories that each contain an example for JSP 1.x.

• make -- Contains example makefiles for servlets. These are common makefiles containing rules that are included by all other makefiles.

• servlets -- Contains subdirectories that each contain Java source files and makefiles for servlet examples.

• sessions -- Contains session manager directories.

The SimpleSession directory contains code for
SimpleSessionManager.java, which is the default servlet session
manager when the iPlanet Web Server runs in single process mode, and
SimpleSession.java, which defines session objects, the sessions
managed by SimpleSessionManager. The source code for
SimpleSessionManager and SimpleSession are provided for you to use
as the starting point for defining your own session managers if desired.

The JdbcSession directory contains JdbcSessionManager.java and
JdbcSession.java, which contain support for sessions stored in a
database using JDBC.

For more information about sessions and session managers, see
Appendix A, “Session Managers.”

• tools -- Contains the SDKTools.jar file and other utility files.

Servlet Examples

This section discusses two servlet examples as follows:

• A Simple Servlet Example -- generates a very simple page to be displayed in
  a web browser.

• Example of a Servlet that Counts Visits -- this servlet is used to count visits
to a web page.

You can find additional examples in the directory server_root/plugins/
samples/servlets/servlets.
These examples are simple, introductory examples. For information about using the Java Servlet API, see the documentation provided by Sun Microsystems at:

A Simple Servlet Example

The following example code defines a very simple servlet. This is the SimpleServlet example in the server_root/plugins/samples/servlets/servlets/SimpleServlet directory.

This servlet generates an HTML page that says "This is output from SimpleServlet." as shown in Figure 2.1.

Figure 2.1 Output from SimpleServlet.class

This example defines the main servlet class as a subclass of HttpServlet and implements the doGet method. The code is shown below:

```java
import java.io.*;
import javax.servlet.*;
import javax.servlet.http.);

public class SimpleServlet extends HttpServlet
{
    public void doGet (HttpServletRequest      request,
        HttpServletResponse     response
    ) throws ServletException, IOException
    {
        PrintWriter             out;
        String                  title = "Simple Servlet Output";

        // set content type and other response header fields first
        response.setContentType("text/html");
```
Example of a Servlet that Counts Visits

The following example code defines a servlet that counts visits to a web page. This is the CounterServlet example in the server_root/plugins/samples/servlets/servlets/Counter directory.

This servlet generates an HTML page that reports the number of visits for an individual user and for all users, as shown in Figure 2.2.

![Output from CounterServlet.class](image)

```
Thank you for coming back. You have visited this page 2 times This page was accessed 2 times total
```

This example defines the main servlet class as a subclass of HttpServlet and implements the doGet method, as the SimpleServlet example did, but it also defines a thread, tracks total hits by reading from and writing to a file, and tracks hits from individual users using a cookie. The code is shown below:

```java
import java.io.*;
import javax.servlet.*;
import javax.servlet.http.*;

public class CounterServlet extends HttpServlet
{
    private File _counterFile = new File("/tmp/CounterServlet.dat");
    private CounterWriterThread _cntWrtThread = new CounterWriterThread();
    private int _cnt = 0;

    private boolean _fTerminating = false;

    public void init (ServletConfig config)
    throws ServletException
    {
        super.init (config);
    }
```
readCounter ();
_cntWrtThread.start ();
}

public class CounterWriterThread
extends Thread
{
public void run ()
{
while (!_fTerminating)
{
writeCounter ();
try {
sleep (1000);
}
catch (Exception ie)
{
}
}
}

private void writeCounter ()
{
DataOutputStream dos = null;
try{
    dos = new DataOutputStream (new FileOutputStream (_counterFile));
    dos.writeInt (_cnt);
}catch (Exception e)
{
}
finally{
    try {
        if (dos != null)
            dos.close ();
    }catch (Exception ioe)
{
}
}
}

private void readCounter ()
{
DataInputStream dis = null;
try{
    dis = new FileInputStream (_counterFile);
    _cnt = dis.readInt ();
}catch (Exception e)
{
}
public void doGet (HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException {

  PrintWriter out;

  // set content type and other response header fields first
  response.setContentType("text/html");

  // then write the data of the response
  out = response.getWriter();

  _cnt++;

  Cookie cookies[] = request.getCookies();
  Integer nof = new Integer (0);

  for(int i = 0; i < cookies.length; i++ )
  {
    if (cookies[i].getName ().equals ("CounterServletCookie"))
    {
      String nofS = cookies[i].getValue ();
      try {
        nof = Integer.valueOf (nofS);
      } catch (Exception nfe) {
        break;
      }
    }

    nof = new Integer (nof.intValue () + 1);
    Cookie c = new Cookie ("CounterServletCookie", nof.toString ());
    c.setMaxAge (3600 * 24 * 365);
    c.setPath   ("/");
    response.addCookie (c);

    out.println("<HTML><BODY><CENTER>");
if (nof.intValue () > 1)
    out.println("Thank you for coming back. You have visited this page <B>"
    + nof + "</B> times");

    out.println("This page was accessed <B>" + _cnt + "</B> times total");
    out.println("</CENTER></BODY></HTML>");

} }

JSP Examples

This section presents the following JSP examples:

• JSP that Accesses the Request Object. This example is self-contained -- it uses no external beans or Java classes.

• JSP that Responds to a Form and Uses Java Beans.

You can find additional examples in the directory server_root/plugins/samples/servlets/jsp.10.

These examples are simple, introductory examples. For information about creating JSPs, see Sun Microsystem’s JavaServer Pages web page at:

JSP that Accesses the Request Object

JavaServer Pages (JSPs) contain both standard HTML tags and JSP tags.

All JSP pages can implicitly access the request object, which contains information about the request that invoked the page, such as the requested URI, the query string, the content type, and so on. The request object has properties such as requestURI, queryString, and contentType.

This example displays information about the current request. It gets all its data from the request object, which is automatically passed to the JSP. This is the snoop.jsp example in the server_root/plugins/samples/servlets/jsp.10/snp directory.
Figure 2.3 shows an example of the output page generated by this JSP.

![Request Information]

Figure 2.3 Output page generated by snoop.jsp

The source code for snoop.jsp is:

```html
<html>
<body bgcolor="white">
<h1> Request Information </h1>
<font size="4">
<%@ page session="false" %>
JSP Request Method: <%= request.getMethod() %>
<br>
Request URI: <%= request.getRequestURI() %>
<br>
Request Protocol: <%= request.getProtocol() %>
<br>
Servlet path: <%= request.getServletPath() %>
<br>
Path info: <%= request.getPathInfo() %>
<br>
Path translated: <%= request.getPathTranslated() %>
<br>
The browser you are using is Mozilla/4.7 [en]C-AOLNSCP (WinNT; U)
```

JSP that Responds to a Form and Uses Java Beans

This example discusses a simple JSP that accesses data on Java beans to respond to a form. This is the example in the server_root/plugins/samples/servlets/jsp.10/checkbox directory.

This example presents a web page, check.html, that displays a form asking the user to select their favorite fruits. The action of the form is checkresult.jsp. This JSP file gets information about the fruits from a Java bean. (Note that Java beans were originally designed for use with visual tool builders, and they have some overhead that can make them slow when used to retrieve data to display in web pages.)

The discussion of this example has the following sections:

• The Form
JSP Examples

- The Output Page Generated by the JSP File
- Accessing Input Parameters
- Using Externally Defined Java Beans
- Source Code for the JSP File

The Form

The form in the page has the following elements:
- Four checkboxes named Apples, Grapes, Oranges, and Melons
- A Submit button

The form’s method is POST and the action is checkresult.jsp. (It also works if the form’s method is GET.)

<FORM TYPE=POST ACTION=checkresult.jsp>

Figure 2.4 shows an example of the form.

![Figure 2.4](image)

Figure 2.4  This form invokes a JSP as its action

The Output Page Generated by the JSP File

The JSP file checkresult.jsp responds to the form. It uses a request and then a bean to access the parameters received from the form.

The output page generated by checkresult.jsp displays the fruits that were selected. The JSP file gets information about the fruits from Java Beans.

This JSP file demonstrates the following features:
- Accessing Input Parameters
- Using Externally Defined Java Beans
Figure 2.5 shows an example of the output from checkresult.jsp:

![Output from checkresult.jsp](image)

Figure 2.5 A JSP page generated in response to a form submission

**Accessing Input Parameters**

JSP pages can extract input parameters when invoked by a URL with a query string, such as when they are invoked as a form action for a form that uses the GET method. The `request.getParameterValues` method retrieves an object that has attributes for each parameter in the query string.

For example, if the following URL is used to invoke a JSP:

```
http://my_domain.com/fruits/checkresult.jsp?Apples=on&Oranges=on
```

The `request` object has properties `Apples` and `Oranges`.

**Using Externally Defined Java Beans**

Some bean objects, including the `request` object, are always available implicitly to a JSP page. Other objects, such as user-defined objects, are not automatically available to the page, in which case you have to include a `<useBean>` tag to tell the page which object to use.
The JSP tag \texttt{<useBean>} creates an instance of an externally defined Java Bean for use within the JSP page. For example, the following code creates an instance of the Java Bean object \texttt{checkbox.CheckTest}, which is defined in \texttt{checktest.html}:

\[
\texttt{<jsp:useBean id="foo" scope="page" class="checkbox.CheckTest"/>}
\]

In this case, the bean instance exists for the duration of the page.

For more information about defining Java Beans, see:

http://java.sun.com/beans/index.html

\section*{Source Code for the JSP File}

Here is the source code for the JSP file \texttt{checkresult.jsp}:

\[
\texttt{<html>}
\]

\[
\texttt{<body bgcolor="white">}
\]

\[
\texttt{<font size=5 color="red">}
\]

\[
\texttt{<%! String[] fruits; %>}
\]

\[
\texttt{<jsp:useBean id="foo" scope="page" class="checkbox.CheckTest"/>}
\]

\[
\texttt{<jsp:setProperty name="foo" property="fruit" param="fruit"/>}
\]

\[
\texttt{<hr>}
\]

\[
\texttt{The checked fruits (got using request) are: <br>}
\]

\[
\texttt{<%}
\]

\[
\texttt{fruits = request.getParameterValues("fruit");}
\]

\[
\texttt{%}
\]

\[
\texttt{<ul>}
\]

\[
\texttt{<%}
\]

\[
\texttt{if (fruits != null) {
}\}}\]

\[
\texttt{for (int i = 0; i < fruits.length; i++) { %}
\]

\[
\texttt{<li>}
\]

\[
\texttt{<%}
\]

\[
\texttt{out.println (fruits[i]);}
\]

\[
\texttt{}}\]

\[
\texttt{else out.println ("none selected"); %}
\]

\[
\texttt{}}</li>
\]

\[
\texttt{<hr>}
\]

\[
\texttt{<br>}
\]

\[
\texttt{<hr>}
\]

\[
\texttt{</ul>}
\]

\[
\texttt{</body>}
\]

\[
\texttt{</html>}
\]
The checked fruits (got using beans) are <br>

```jsp
tfruits = foo.getFruit();
<ul>
<li>
<% 
    if (!fruits[0].equals("1")) {
        for (int i = 0; i < fruits.length; i++) {
            out.println (fruits[i]);
    }
} else out.println ("none selected");
%</li>
</ul>
```

```html
</html>
```
Session objects maintain state and user identity across multiple page requests over the normally stateless HTTP protocol. A session persists for a specified time period, across more than one connection or page request from the user. A session usually corresponds to one user, who may visit a site many times. The server can maintain a session either by using cookies or by rewriting URLs. Servlets can access the session objects to retrieve state information about the session.

This appendix has the following sections:
- Session Overview
- Specifying a Session Manager
- SimpleSessionManager
- MMapSessionManager
- JdbcSessionManager
- How Do Servlets Access Session Data?

**Session Overview**

An HTTP session represents the server's view of the session. The server considers a session new under these conditions:

- The client does not yet know about the session.
• The session has not yet begun.

A session manager automatically creates new session objects whenever a new
session starts. In some circumstances, clients do not join the session, for
example, if the session manager uses cookies and the client does not accept
cookies.

**Note**

The session ID generator, which is used for servlet sessions, employs
cryptographically strong unique random number generation algorithms. This
may present a performance problem on older, slow machines. The Session
Manager API allows you to redefine the random ID generation method and
customize it to your particular needs (see the `SimpleSessionManager.java`
example file described in “Source Code for SimpleSessionManager” on
page 47).

iPlanet Web Server 4.1 comes with three session managers for creating and
managing sessions:

• `SimpleSessionManager` -- the default session manager when the server
  runs in single process mode.
• `MMapSessionManager` -- the default session manager when the server runs
  in multi-process mode.
• `JdbcSessionManager` -- a session manager that stores session information
  in a database using the JDBC API.

iPlanet Web Server 4.1 also allows you to develop your own session managers
and load them into the server. The build includes the source code for
`SimpleSessionManager` and the session object it manages, `SimpleSession`.
The source code files for these classes are provided as a starting point for you
to define your own session managers if desired. These Java files are in the
directory `server_root/plugins/samples/servlets/sessions/`
`SimpleSession`.

The build also includes the source code for `JdbcSessionManager` and the
session object it manages, `JdbcSession`. These Java files are in the directory
`server_root/plugins/samples/servlets/sessions/JdbcSession`. 
Specifying a Session Manager

By default, if the iPlanet Web Server starts in single process mode, it uses SimpleSessionManager as the session manager for servlets. If it starts in multi-process mode, it uses MMapSessionManager. For more information about single process mode versus multi-processes mode, see Chapter 7, “Configuring Server Preferences,” in the iPlanet Web Server Administrator’s Guide. In addition, you can read about the MaxProcs parameter in the magnus.conf file in the NSAPI Programmer’s Guide for iPlanet Web Server.

You can change the session manager in any of the following ways:

• Use the Servlets>Configure Global Servlet Attributes page in the Server Manager interface.
  In the Session Manager field, specify the session manager, and, if appropriate, specify parameters for the session manager in the Session Manager Args field.

• Edit the file servlets.properties in the directory server_id/config.
  Add a line specifying a value for servlets.sessionmgr and, if appropriate, also add a line specifying the parameters for the session manager. For example:

  servlets.sessionmgr=com.netscape.server.http.session.YourSesMgr
  servlets.sessionmgr.initArgs=maxSessions=20,timeOut=300,reapInterval=150

• Edit the file contexts.properties in the directory server_id/config.
  Add a line specifying a value for context.context_name.sessionmgr and, if appropriate, also add a line specifying the parameters for the session manager. For example:

  context.global.sessionmgr=com.netscape.server.http.session.YourSesMgr
  context.global.sessionmgr.initArgs=maxSessions=20,timeOut=300

  You can change the global context or define a new context and assign specific servlets to it. For more information, see Appendix C, “Properties Files.”
The SimpleSessionManager works only in single process mode. It is loaded by default if the iPlanet Web Server starts in single-process mode when a SessionManager is not specified in the servlets.properties or contexts.properties configuration file. These sessions are not persistent, that is, all sessions are lost when the server is stopped.

Parameters

The SimpleSessionManager class takes the following parameters:

- **maxSessions** - the maximum number of sessions maintained by the session manager at any given time. The session manager refuses to create any more new sessions if there are already maxSessions number of sessions present at that time. The default value is 1000.

- **timeOut** - the amount of time in seconds after a session is accessed by the client before the session manager destroys it. Those sessions that haven’t been accessed for at least timeOut seconds are destroyed by the reaper method. The default value is 1800 (30 minutes).

- **reapInterval** - the amount of time in seconds that the SessionReaper thread sleeps before calling the reaper method again. The default value is 600 (10 minutes).

Enabling SimpleSessionManager

You may want to enable SimpleSessionManager to change its default parameters. You can also enable SimpleSessionManager for a particular context if the server is running in multi-process mode. To enable the iPlanet Web Server to use SimpleSessionManager, do any of the following:

- Use the Servlets>Configure Global Servlet Attributes page in the Server Manager interface.
  
  In the Session Manager field specify:

  com.netscape.server.http.session.SimpleSessionManager
You can also specify parameters for the session manager in the Session Manager Args field, for example:

\[
\text{maxSessions=}20, \text{timeOut=}300, \text{reapInterval=}150
\]

- Edit the file `servlets.properties` in the directory `server-id/config`.
  Add a line specifying a value for `servlets.sessionmgr` and a line specifying the parameters for the session manager:

\[
\text{servlets.sessionmgr}=\text{com.netscape.server.http.session.SimpleSessionManager}
\]

\[
\text{servlets.sessionmgr.initArgs}=\text{maxSessions=}20, \text{timeOut=}300, \text{reapInterval=}150
\]

- Edit the file `contexts.properties` in the directory `server-id/config`.
  Add a line specifying a value for `context.context_name.sessionmgr` and a line specifying the parameters for the session manager:

\[
\text{context.global.sessionmgr}=\text{com.netscape.server.http.session.SimpleSessionManager}
\]

\[
\text{context.global.sessionmgr.initArgs}=\text{maxSessions=}20, \text{timeOut=}300, \text{reapInterval=}150
\]

You can change the global context or define a new context and assign specific servlets to it. For more information, see Appendix C, “Properties Files.”

**Source Code for SimpleSessionManager**

The `SimpleSessionManager` creates a `SimpleSession` object for each session. The source files for `SimpleSessionManager.java` and `SimpleSession.java` are in the directory `server_root/plugins/samples/servlets/sessions/SimpleSession`.

The source code files for `SimpleSessionManager.java` and `SimpleSession.java` are provided so you can use them as the starting point for defining your own session managers and session objects. These files are very well commented.

`SimpleSessionManager` extends `NSHttpSessionManager`. The class file for `NSHttpSessionManager` is in the JAR file `NSServletLayer.jar` in the directory `server_root/bin/https/jar`. The `SimpleSessionManager` implements all the methods in `NSHttpSessionManager` that need to be implemented, so you can use `SimpleSessionManager` as an example of how to extend `NSHttpSessionManager`. When compiling your subclass of `SimpleSessionManager` or `NSHttpSessionManager`, be sure that the JAR file `NSServletLayer.jar` is in your compiler's classpath.
**MMapSessionManager**

This is a persistent memory map (mmap) file based session manager that works in both single process and multi-process mode. It can be used for sharing session information across multiple processes possibly running on different machines. It is loaded by default if the iPlanet Web Server starts in multi-process mode when a session manager is not specified in the `servlets.properties` or `contexts.properties` configuration file.

**Parameters**

`MMapSessionManager` takes the following parameters:

- **maxSessions** - the maximum number of sessions maintained by the session manager at any given time. The session manager refuses to create any more new sessions if there are already `maxSessions` number of sessions present at that time. The default value is 1000.

- **maxValuesPerSession** - the maximum number of values or objects a session can hold. There is no limit.

- **maxValuesSize** - the maximum size of each value or object that can be stored in the session. There is no limit.

- **timeOut** - the amount of time in seconds after a session is last accessed by the client before the session manager destroys it. Those sessions that haven’t been accessed for at least `timeOut` seconds are destroyed by the `reaper` method. The default value is 1800 (30 minutes).

- **reapInterval** - the amount of time in seconds that the `SessionReaper` thread sleeps before calling the `reaper` method again. The default value is 600 (10 minutes).

**Enabling MMapSessionManager**

You may want to enable `MMapSessionManager` to change its default parameters. You can also enable `MMapSessionManager` for a particular context if the server is running in single process mode. To enable iPlanet Web Server to use `MMapSessionManager`, do any of the following:
JdbcSessionManager

- Use the Servlets>Configure Global Servlet Attributes page in the Server Manager interface.
  
  In the Session Manager field specify:
  
  ```java
  com.netscape.server.http.session.MMapSessionManager
  ```
  
  You can also specify parameters for the session manager in the Session Manager Args field, for example:
  
  ```java
  maxSessions=20,maxValueSize=1024,timeOut=300,reapInterval=150
  ```
  
- Edit the file `servlets.properties` in the directory `server-id/config`.
  
  Add a line specifying a value for `servlets.sessionmgr` and a line specifying the parameters for the session manager:
  
  ```java
  servlets.sessionmgr=com.netscape.server.http.session.MMapSessionManager
  servlets.sessionmgr.initArgs=maxSessions=20,maxValueSize=1024,timeOut=300,reapInterval=150
  ```
  
- Edit the file `contexts.properties` in the directory `server-id/config`.
  
  Add a line specifying a value for `context.context_name.sessionmgr` and a line specifying the parameters for the session manager:
  
  ```java
  context.global.sessionmgr=com.netscape.server.http.session.MMapSessionManager
  context.global.sessionmgr.initArgs=maxSessions=20,maxValueSize=1024,timeOut=300,reapInterval=150
  ```
  
  You can change the global context or define a new context and assign specific servlets to it. For more information, see Appendix C, “Properties Files.”

This session manager can only store objects that implement `java.io.Serializable`.

JdbcSessionManager

This is a persistent JDBC-based session manager that works in both single process and multi-process modes. It can be used to store sessions in a custom database, which can then be shared across multiple processes possibly running on different machines.

This sample JDBC session manager is not written, tested, or intended for production use. It is provided so that you can customize its behavior to suit your own needs.
JdbcSessionManager has been tested with a standard JDBC-ODBC driver against Microsoft SQL Server 7.0SP1. You must set up the ODBC source, database, and table for the session manager to use. It is recommended that the Session ID column be indexed for higher lookup performance.

**Parameters**

JdbcSessionManager takes the following parameters:

- **timeout** - the amount of time in seconds after a session is accessed by the client before the session manager destroys it. Those sessions that haven’t been accessed for at least `timeout` seconds are destroyed by the reaper method. The default value is 1800 (30 minutes).

- **provider** - the JDBC driver (the default is `sun.jdbc.odbc.JdbcOdbcDriver`). For more information about the JDBC API, see the following web site:

- **url** - the data source (the default is `jdbc:odbc:LocalServer`).

- **table** - name of the SQL table that store sessions (the default is `sessions`).

- **username** - the login username for the database.

- **password** - the login password for the database.

- **reaperActive** - tells the session manager whether to run session reaper to remove expired sessions from the database when `true`, which is the default value. It is recommended that only one server in the cluster be running the reaper.

- **accessTimeColumn** - the name of the column that holds the last access time in minutes (the default name is `AccessTime`). The SQL type is `NUMERIC(9)`.

- **sessionIdColumn** - the name of the column that holds the session ID (the default name is `SessionID`). The SQL type is `VARCHAR(100)`.

- **valueColumn** - the name of the column that holds the session object (the default name is `Value`). The SQL type is `VARBINARY(4096)`. This column must be large enough to accommodate all your session data.
Each type of operation on the database that handles session information (looking up, inserting, updating, and deleting) is performed by a corresponding dedicated connection. Each of these connections has a precompiled SQL statement for higher performance. The following parameters allow you to customize the number of dedicated connections that perform each of the operations.

- **lookupPool** - the number of connections that perform lookup operations (the default is 4 connections).
- **insertPool** - the number of connections that perform insert operations (the default is 4 connections).
- **updatePool** - the number of connections that perform update operations (the default is 4 connections).
- **deletePool** - the number of connections that perform delete operations (the default is 2 connections).

## Enabling JdbcSessionManager

You may want to enable JdbcSessionManager to change its default parameters. You can also enable JdbcSessionManager for a particular context if the server is running in single process mode. To enable iPlanet Web Server to use JdbcSessionManager, do any of the following:

- Use the Servlets>Configure Global Servlet Attributes page in the Server Manager interface.
  
  In the Session Manager field specify:

  ```
  com.netscape.server.http.session.JdbcSessionManager
  ```

  You can also specify parameters for the session manager in the Session Manager Args field, for example:

  ```
  timeOut=1200,username=mysession,password=mypassword
  ```

- Edit the file `servlets.properties` in the directory `server-id/config`.
  
  Add a line specifying a value for `servlets.sessionmgr` and a line specifying the parameters for the session manager:

  ```
  servlets.sessionmgr=com.netscape.server.http.session.JdbcSessionManager
  servlets.sessionmgr.initArgs=timeOut=1200,username=mysession,password=mypassword
  ```
Edit the file contexts.properties in the directory server-id/config.

Add a line specifying a value for context.context_name.sessionmgr and a line specifying the parameters for the session manager:

```
custom.global.sessionmgr=com.netscape.server.http.session.JdbcSessionManager
custom.global.sessionmgr.initArgs=timeOut=1200,username=mysession,password=mypassword
```

You can change the global context or define a new context and assign specific servlets to it. For more information, see Appendix C, "Properties Files."

This session manager can only store objects that implement java.io.Serializable.

**Source Code for JDBC SessionManager**

The JdbcSessionManager creates a JdbcSession object for each session. The source files JdbcSessionManager.java and JdbcSession.java are in the directory server_root/plugins/samples/servlets/sessions/JdbcSession.

The source code files, JdbcSessionManager.java and JdbcSession.java, are provided so you can use them as the starting point for defining your own session managers and session objects. These files are very well commented.

JdbcSessionManager extends NSHttpSessionManager. The class file for NSHttpSessionManager is in the JAR file NSServletLayer.jar in the directory server_root/bin/https/jar. The JdbcSessionManager implements all the methods in NSHttpSessionManager that need to be implemented, so you can use JdbcSessionManager as an example of how to extend NSHttpSessionManager. When compiling your subclass of JdbcSessionManager or NSHttpSessionManager, be sure that the JAR file NSServletLayer.jar is in your compiler's classpath.
How Do Servlets Access Session Data?

To access the state information stored in a session object, your servlet can create a new session as follows:

```java
// request is an HttpServletRequest that is passed to the servlet
SessionClass session = request.getSession(true);
```

The servlet can call any of the public methods in `javax.servlet.http.HttpSession` on the session object. These methods include (among others):

- `getCreationTime`
- `getId`
- `getLastAccessedTime`
- `getMaxInactiveInterval`
- `getValue`

For more information about the classes `HttpServletRequest` and `HttpSession`, see Sun Microsystem’s API Servlets Documentation at:

How Do Servlets Access Session Data?
Appendix B

Servlet Settings in obj.conf

The iPlanet Web Server 4.1 Administration Server automatically modifies the file obj.conf in the config directory to load the servlet engine if servlets are enabled. Whenever you make changes to servlet settings by using the Server Manager interface, the system automatically updates obj.conf appropriately.

However, in case you are interested in the settings that affect servlets, this appendix describes the directives in obj.conf and value settings in mime.types that are relevant to servlets.

Directives for Enabling Servlets

The following directives in the init section of obj.conf load and initialize the servlet engine to enable servlets (for Windows NT):

```
Init fn="load-modules" shlib="server_root/bin/https/bin/
NSServletPlugin.dll"
funcs="NSServletEarlyInit,NSServletLateInit,NSServletNameTrans,
NSServletService" shlib_flags="(global|now)"
Init fn="NSServletEarlyInit" EarlyInit=yes
Init fn="NSServletLateInit" LateInit=yes
```

for Unix, the directives are the same except for the following line:

```
Init fn="load-modules" shlib="server_root/bin/https/lib/
libNSServletPlugin.so"
```
NSServletEarlyInit takes an optional parameter cache_dir that specifies the location of a temporary cache directory for JSP classes. By default, the directory is named ClassCache and goes under your server root directory.

NSServletLateInit takes an optional parameter CatchSignals that specifies whether or not Java thread dumps are logged. The value is yes or no.

NSServletService takes two optional parameters, servlet="servlet_name" and context="context_name". These parameters allow you to define objects in obj.conf that generate responses for specific servlets or contexts. You can use one or both parameters in a directive. The servlet or context must be defined in the servlets.properties or contexts.properties file. You can define an object that pertains to a particular servlet, a particular servlet context, or both, as follows:

<Object name="MyServlet">
  Service fn="NSServletService" context="MyServletContext"
  servlet="MyServletName"
</Object>

For an example of the basic use of NSServletService, see the discussion of Service examples in Chapter 2, “Syntax and Use of Obj.conf” in the NSAPI Programmer’s Guide for iPlanet Web Server.

When servlets are enabled, the following directive appears in the default object:

NameTrans fn="NSServletNameTrans" name="servlet"

This directive is used for servlet virtual path translations and for the URI cache. Do not delete this line when servlets are enabled.

Also, obj.conf always has the following objects, which you should not delete:

<Object name="servlet">
  Service fn="NSServletService"
</Object>

<Object name="jsp">
  Service fn="NSServletService"
</Object>

If you delete these objects, you can no longer use the Server Manager interface to enable servlets and modify servlet settings.

For more information, see the NSAPI Programmer’s Guide for iPlanet Web Server.
Directives for Registered Servlet Directories

For each registered servlet directory, the default object in `obj.conf` has a `NameTrans` directive that assigns the name `ServletByExt` to all requests to access that directory. For example:

```
NameTrans fn="pfx2dir" from="/servlet" dir="D:/Netscape/Server4/docs/servlet" name="ServletByExt"
```

A separate object named `ServletByExt` has instructions for processing requests for servlets:

```
<Object name="ServletByExt">
  ObjectType fn="force-type" type="magnus-internal/servlet"
  Service type="magnus-internal/servlet" fn="NSServletService"
</Object>
```

Do not delete this object, even if no servlet directories are currently registered. If this object is deleted, you can no longer use the Server Manager interface to register servlet directories.

JSP

The following line in `mime.types` sets the type for files with the extension `.jsp`:

```
type=magnus-internal/jsp exts=jsp
```

When JSP is enabled, the following directive in `obj.conf` handles the processing of requests for files of type `magnus-internal/jsp` (that is, JSP files):

```
Service fn="NSServletService" type="magnus-internal/jsp"
```
This appendix discusses the purpose and use of the files
`servlets.properties`, `rules.properties`, and `contexts.properties`,
which reside in the directory `server_id/config`.

**servlets.properties**

The *servlets.properties* file defines global servlet settings and the list of
servlets in the system.

Examples of global servlet settings are which servlet to run when the iPlanet
Web Server starts up, the reload interval for servlets, and so on. The
*servlets.properties* file also specifies configuration information for
individual servlets. Configuration information includes the class name, the
classpath, and any input arguments required by the servlet.

If you want to specify a virtual path translation for a servlet, the servlet must be
configured in the *servlets.properties* file.

You can specify configuration information for servlets either by using the
Servlets>Configure Servlet Attributes page in the Server Manager interface or by
editing *servlets.properties* directly. Whenever you make a change in the
Servlets>Configure Servlet Attributes page in the Server Manager interface, the
system automatically updates *servlets.properties*.
When specifying attributes for a servlet, you specify a name parameter for the servlet. This name does not have to be the name of the class file for the servlet; it is an internal identifier for the servlet. You specify the name of the class file as the value of the code parameter.

Here is a sample servlets.properties file:

```
servlets.properties
# Servlets Properties
# servlets to be loaded at startup
servlets.startup= hello
# the reload interval for dynamically-loaded servlets and JSPs
# (default is 10 seconds)
servlets.config.reloadInterval=5
# the default document root,
# needed so ServletContext.getRealPath will work
servlets.config.docRoot=E:/Netscape/Server4/docs
# the session manager
servlets.sessionmgr=com.netscape.server.http.session.SimpleSessionManager
# tracker servlet
servlet.tracker.code=MyTrackerServlet
servlet.trackerclasspath=D:/Netscape/Server4/docs/servlet
# demo1 servlet
servlet.demo1.code=Demo1Servlet
servlet.demo1.classpath=D:/Netscape/Server4/docs/demos
servlet.demo1.initArgs=a1=0,b1=3456
servlet.demo1.context=context1
```

The rules.properties file defines servlet virtual path translations. For example, you could set up a mapping so that the URL pointing to /mytest2 invokes the servlet named demo1 in the servlets.properties file. You can specify virtual paths for your servlets either by setting parameters in the Servlets>Configure Servlet Virtual Path Translation page of the Server Manager interface or by specifying the paths in the rules.properties file.

Note that the name associated with the servlet in servlets.properties is used in the file rules.properties -- the class name of the servlet does not show up in rules.properties. For example, the following lines in servlets.properties associate the servlet name demo1 with the servlet class file Demo1Servlet.class in the directory D:/Netscape/Server4/docs/demos.
contexts.properties

# in servlets.properties
# demo1 servlet
servlet.demo1.code=Demo1Servlet
servlet.demo1.classpath=D:/Netscape/Server4/docs/demos

The following line in rules.properties defines a servlet virtual path
translation such that the URL http://server-name/mytest2 invokes the servlet
at D:/Netscape/Server4/docs/demos/Demo1Servlet.class.

/mytest2=demo1

Here is an example of rules.properties.

rules.properties

# Servlet rules properties
# This file specifies the translation rules for invoking servlets.
# The syntax is:
# /virtual-path=servlet-name
# where virtual-path is the virtual path used to invoke the servlet,
# and servlet-name is the name of the servlet as specified in
# servlets.properties.
# Surrounding white space is ignored.
# The ordering of the rules is not important, as the longest
# match is always used first.
/mytest1=tracker
/mytest2=demo1

contexts.properties

The contexts.properties file defines contexts, which allow multiple servlets
to exchange data and access each other’s fields. Contexts are useful for defining
virtual servers or for code isolation. If no contexts are defined, the default
global context is used for all servlets.

If the context for a servlet is not defined, the servlet belongs to the global
context. You can use the same servlet in multiple contexts.

Only the name of a context is required. Any other unspecified properties are
inherited from the global context. You can also change the properties of the
global context. The comments in the contexts.properties file list the default
property values of the global context.

Here is an example of contexts.properties.
contexts.properties

contexts.properties
# @(#)contexts.properties (autogenerated)
#
# Contexts Properties:
#
# context.<context_name>.sessionmgr=session manager (some session managers
# (like MMapSessionManager) can only be instantiated once within the
# server
# context.<context_name>.sessionmgr.initArgs=list of (name, value) pairs which
# will represent parameters specific to the session manager
# context.<context_name>.initArgs=list of (name, value) pairs which will be added
# to this context’s attributes
# context.<context_name>.realPathFromRequest={true|false} tells the server whether
# to calculate getRealPath based on docRoot of the context or try to go
# through normal NSAPI steps
# context.<context_name>.respondCookieVersion={cookie version} tells the server
# whether to respond with specific cookie version
# context.<context_name>.sessionExpireOnClose={true|false} tells the server to mark
# session cookies as directed to expire when the user quits the browser
# context.<context_name>.includeTransparency={true|false} tells the server whether
# to try to honor setting headers from the included servlet
# context.<context_name>.tempDir=path (forward slashes only) - sets up Servlet API
# 2.2 property for the temporary directory
# context.<context_name>.reloadInterval=seconds - time interval within which the
# server checks for jsp and servlet files being modified (global context
# only)
# context.<context_name>.javaBufferSize=bytes (deprecated)
# context.<context_name>.bufferSize=bytes - initial http output stream buffer size
# context.<context_name>.docRoot=path (forward slashes only) - this context
# document root when not specified - web server’s document root will be
# used (default)
# context.<context_name>.inputStreamLengthCheck={true|false} - makes
# ServletInputStream to stop reading data, when Content-Length bytes are
# read
# context.<context_name>.outputStreamFlushTimer=(seconds|0) - forces the stream to
# flush the data if certain time elapsed since the last flush; 0 - ignore
# it
# context.<context_name>.uri=contex_uri_base - additional URI prefix which
# services as a context base
# context.<context_name>.host=hostname
# context.<context_name>.ip=ip
# context.<context_name>.authdb=name - authentication database
# context.<context_name>.classpath=name - global classpath for this context
# context.<context_name>.singleClassLoader={true|false} - tells the servlet engine
# whether to use a single class loader for all servlets in the context
# context.<context_name>.serverName=name - server instance name
# context.<context_name>.contentTypeIgnoreFromSSI={true|false} - ignore
# setContentType when invoked from SSI
# context.<context_name>.parameterEncoding=(utf8,none,auto) - advises the web
# server on how to decode parameters from forms
#
# <context_name>="global" is reserved for the global context. Every new context
# will inherit initial settings of the global context
#
# Context properties:
contexts.properties

# context.global.sessionmgr=com.netscape.server.http.session.SimpleSessionManager
# context.global.sessionmgr.initArgs=
# context.global.initArgs=initial=0
# context.global.realPathFromRequest=false
# context.global.respondCookieVersion=0
# context.global.sessionExpireOnClose=false
# context.global.includeTransparency=true
# context.global.tempDir=/tmp
# context.global.reloadInterval=5
# context.global.javaBufferSize=0
# context.global.bufferSize=4096
# context.global.docRoot=/foo/bar
# context.global.inputStreamLengthCheck=true
# context.global.outputStreamFlushTimer=0
# context.global.uri=/
# context.global.host=
# context.global.ip=
# context.global.authdb=default
# context.global.classpath=
# context.global.singleClassLoader=false
# context.global.contentTypeIgnoreFromSSI=true
# context.global.parameterEncoding=utf8
#
# # contexts
# context.context1.name=context1
contexts.properties
The Java Virtual Machine (JVM) works by default without any additional configuration if properly set up.

However, if you need to specify settings for the JVM, such as additional classpath information, you can configure the JVM properties for iPlanet Web Server via the Administrator interface. You can add as many other properties as you want to (up to 64).

You can also configure JVM parameters by editing the `jvm12.conf` configuration file, which resides under the server's `config` directory.

For example, to disable JIT, you can add the following line to `jvm12.conf`:

```ini
java.compiler=DISABLED
```

Here is an example `jvm12.conf` file. The `jvm.classpath` value is all on one line in the actual file.

```ini
[JVMConfig]
#jvm.minHeapSize=1048576
#jvm.maxHeapSize=16777216
#jvm.enableClassGC=0
#jvm.verboseMode=1
#jvm.enableDebug=1
#jvm.printErrors=0
#jvm.option=-Xrunoii
#jvm.profiler=optimizeit
```
Generally you should use plain property options (like name=value) for the JDK1.2 configuration and jvm.option=options for JVM-vendor dependent configurations. There can be multiple occurrences of jvm.option parameters.

The jvm12.conf file has a configuration parameter, jvm.stickyAttach. Setting the value of this parameter to 1 causes threads to remember that they are attached to the JVM, thus speeding up request processing by eliminating AttachCurrentThread and DetachCurrentThread calls. It can, however, have a side-effect: recycled threads which may be doing other processing can be suspended by the garbage collector arbitrarily.

Thread pools can be used to eliminate this side effect for other subsystems. For more information about thread pools, see “Adding and Using Thread Pools” in Chapter 7, “Configuring Server Preferences,” in the iPlanet Web Server Administrator’s Guide.

For information about JVM, see The Java Virtual Machine Specification from Sun at:

This appendix gives guidelines for debugging servlets and JSPs in iPlanet Web Server 4.1.

Servlet Debugging

iPlanet Web Server 4.1 ships with the Java Runtime Environment (JRE) but not the Java Development Kit (JDK) due to licensing restrictions. However, during installation, you can select an option that tells the server to use a JDK if there is one installed elsewhere on your system.

If the server has been instructed to use a JDK, you can do remote servlet debugging. If the server is using the JRE, you need to switch it to using the JDK before you can do remote debugging. For information on instructing the server to use the JDK or the JRE, see the section “Configuring JRE/JDK Paths” on page 22.
Assuming that the server is using the JDK, you can enable remote debugging by following these steps:

1. Make sure that the server is running in single-process mode. Single-process mode is the default, but you can check in the file magnus.conf to make sure that the MaxProcs parameter is not set to a value greater than 1. If you do not see a setting for MaxProcs in magnus.conf, the default value of 1 is enabled for it.

   For more information about single process mode versus multi-process mode, see Chapter 7, “Configuring Server Preferences,” in the iPlanet Web Server Administrator’s Guide.

2. Set the following parameters in jvm12.conf as appropriate:

   ```
   jvm.enableDebug=1
   java.compiler=NONE
   ```

3. In addition, on some platforms, you may be required to specify the bootclasspath. For example, for Solaris platforms, if Java 1.2 is in /java, you set it as:

   ```
   jvm.option=-Xbootclasspath:/java/lib/tools.jar:/java/jre/lib/rt.jar
   ```

4. Start the server manually and record the password for remote debugging (this is displayed on the console).

5. Start the Java debugger:

   ```
   jdb -host your_host -password the_password
   ```

   You should be able to debug your Java classes now using the jdb command.

---

**JSP Debugging**

iPlanet Web Server 4.1 uses a public domain JSP compiler developed as part of Apache Software Foundation’s Jakarta project. The Jakarta project develops a servlet engine called Tomcat, which includes a JSP compiler called Jasper. The version of the JSP compiler is taken from the Tomcat 3.0 Milestone release. Subsequent versions of iPlanet Web Server will use later versions of the Jasper JSP compiler. For more information, see the following web site:

http://jakarta.apache.org/
JSP Debugging

iPlanet Web Server 4.1 uses a native servlet engine, but uses the Jasper JSP compiler for compiling a JSP page into a servlet. Jasper and iPlanet Web Server 4.1 are not tightly integrated, so you might need to edit the JVM Classpath (in the Configure JVM Attributes page of the Server Manager or in the jvm12.conf file) when deploying JSPs using Tag Libraries, beans, and so on.

For information about how to enable JSPs, see “Activating Servlets and JSP” on page 15.

You can debug your JSPs by following these steps:

1. Make sure that the server is running in single-process mode. Single-process mode is the default, but you can check in the file magnus.conf to make sure that the MaxProcs parameter is not set to a value greater than 1. If you do not see a setting for MaxProcs in magnus.conf, the default value of 1 is enabled for it.

   For more information about single process mode versus multi-process mode, see Chapter 7, “Configuring Server Preferences,” in the iPlanet Web Server Administrator’s Guide.

2. Set the following parameters in jvm12.conf as appropriate:

   ```
   java.compiler=NONE
   jvm.trace=6
   nes.jsp.enabledebug=1
   ```

   Setting java.compiler=NONE includes line numbers of the Java source code in the verbose output of the log files. Setting jvm.trace=6 enables verbose output from the JSP compiler and the servlet engine. Setting nes.jsp.enabledebug=1 makes iPlanet Web Server 4.1 generate debuggable Java servlets from the JSPs.
JSP Debugging
You can use Optimizeit! 3.0 from Intuitive Systems to perform remote profiling on the iPlanet Web Server to discover bottlenecks in server-side performance.

You can purchase Optimizeit! from Intuitive Systems at:

http://www.optimizeit.com/index.html

Once Optimizeit! is installed using the following instructions, it becomes integrated into iPlanet Web Server 4.1.

To enable remote profiling, make the following modifications in the jvm12.conf files as appropriate:

jvm.enableClassGC=0  
jvm.option=-Xrunoi # this is only required for JDK1.2  
jvm.profiler=optimizeit  
java.compiler=NONE  
OPTITDIR=optimizeit_root_dir/OptimizeIt30D

When the server starts up with this configuration, you can attach the profiler (for further details see the Optimizeit! documentation).

Also, update the PATH and NSES_CLASSPATH system variables to include the profiler's own jar files and dll files.

Note If any of the configuration options are missing or incorrect, the profiler may experience problems that affect the performance of the iPlanet Web Server.
This appendix clarifies the way some of the standard Servlet API methods work in iPlanet Web Server 4.1. For the official documentation for the methods discussed here (and for all servlet API methods) see the Servlets API Class Reference published by Sun Microsystems at:

This appendix provides clarifications for using the following methods with iPlanet Web Server 4.1:

- HttpServletRequest.getRequestURL
- HttpSession.setMaxInactiveInterval
- GenericServlet.getInitParameter and getInitParameterNames
- ServletContext.getAttributeNames
- ServletContext.getContext
- ServletRequest.getAttribute
- RequestDispatcher.forward and include
- Request.getInputStream and getReader

**HttpRequest.getRequestURL**

```java
public static StringBuffer getRequestURL(HttpServletRequest request);
```
This method reconstructs the URL used by the client to make the given request on the server. This method accounts for difference in scheme (such as http, https) and ports, but does not attempt to include query parameters.

This method returns a StringBuffer instead of a String so that the URL can be modified efficiently by the servlet.

**Clarification**

To determine the server name part of the requested URL, iPlanet Web Server first tries to use the “Host” header and then looks at the value of ServerName in magnus.conf. By default, the server name is the machine name, but this value is editable during iPlanet Web Server 4.1 installation. If the server name has been changed, HttpServletRequest.getRequestURL might not return the host name that is needed to reconstruct the request.

For example, suppose the request is http://abc/index.html. However, the server name has been changed to xyz. In this case, HttpServletRequest.getRequestURL might return http://xyz/index.html, which is not the original URL that was requested.

**HttpSession.setMaxInactiveInterval**

```java
public void setMaxInactiveInterval(int interval);
```

Sets the amount of time that a session can be inactive before the servlet engine is allowed to expire it.

**Clarification**

It is not possible to set the maximum inactive interval so that the session never times out. The session always has a timeout value.

If you pass a negative or zero value, the session expires immediately.
**GenericServlet.getInitParameter and getInitParameterNames**

```java
public String getInitParameter(String name);
```

This method returns a String containing the value of the servlet’s named initialization parameter, or null if this parameter does not exist.

```java
public Enumeration getInitParameterNames();
```

This method returns an enumeration of String objects containing the names of the initialization parameters for the calling servlet. If the calling servlet has no initialization parameters, `getInitParameterNames` returns an empty enumeration.

**Clarification**

For servlets running on iPlanet Web Server 4.1, the methods `getInitParameter` and `getInitParameterNames` for the class `ServletConfig` only work for servlets that are invoked through virtual path translations. The same restriction applies to the convenience methods of the same names in the class `GenericServlet`, which invoke the corresponding methods on `ServletConfig`.

For information about setting virtual path translations, see the section “Specifying Servlet Virtual Paths” on page 19.

These methods do not work if the servlet is invoked by a client request that specifies a servlet in a registered servlet directory rather than using a virtual path translation to access the servlet.

**ServletContext.getAttributeNames**

```java
public java.util.Enumeration getAttributeNames()
```

This method returns an enumeration containing the attribute names available within the servlet’s context.
Clarification

If you are using MMapSessions, iPlanet Web Server truncates names retrieved by ServletContext.getAttributeNames to 128 characters.

ServletContext.getContext

public ServletContext getContext(String uripath);

Returns the servlet context object that contains servlets and resources for a particular URI path, or null if a context cannot be provided for the path.

Clarification

This method only works if both the following conditions are true:

• The servlet whose context is being obtained (that is, the servlet pointed to by uripath) has been configured either through the Servlets>Configure Servlet attributes property of the Server Manager interface or by editing servlets.properties.

• The servlet whose context is being obtained has been loaded.

iPlanet Web Server 4.1 does not load a servlet specified by a URI when getContext is called from another servlet to get the context of an unloaded servlet.

ServletRequest.getAttribute

public java.lang.Object getAttribute(java.lang.String name)

Returns the value of the named attribute as an object, or returns null if no attribute of the given name exists.

Clarification

ServletRequest.getAttribute returns a CGI variable if it exists. However, the getAttributeNames method does not show these variables within its enumeration.
RequestDispatcher.forward and include

public void forward(ServletRequest request, ServletResponse response) throws ServletException, IOException;

Used for forwarding a request from this servlet to another resource on the web server. This method is useful when one servlet does preliminary processing of a request and wants to let another object generate the response.

The request object passed to the target object will have its request URL path and other path parameters adjusted to reflect the target URL path of the target object.

You cannot use this method if a ServletOutputStream object or PrintWriter object has been obtained from the response. In that case, the method throws an IllegalStateException.

public void include(ServletRequest request, ServletResponse response) throws ServletException, IOException;

Used for including the content generated by another server resource in the body of a response. In essence, this method enables programmatic server-side includes. The request object passed to the target object reflects the request URL path and path info of the calling request. The response object only has access to the calling servlet's ServletOutputStream object or PrintWriter object.

An included servlet cannot set headers. If the included servlet calls a method that needs to set headers (such as cookies), the method is not guaranteed to work. As a servlet developer, you must ensure that any methods that might need direct access to headers are properly resolved. To ensure that a session works correctly, start the session outside the included servlet, even if you use session tracking.

Clarification

In iPlanet Web Server 4.1, the dispatcher.forward method may or may not throw an IllegalStateException when either Writer or OutputStream have been obtained. This behavior follows the 2.2 draft and is needed for JSP error page handling. It throws the exception only if the actual data has been flushed out and sent to the client. Otherwise, the data pending in the buffer is simply discarded.
There are two ways for a servlet to read the raw data posted by a client:

- by obtaining the `InputStream` through the `request.getInputStream` method, an older method.
- by obtaining a `BufferedReader` through the `request.getReader` method, a method in use since 2.0.

**Clarification**

A servlet hangs if it attempts to use an `InputStream` to read more data than is physically available. (To find how much data is available, use `request.getContentLength`.) However, if the servlet reads data using a `BufferedReader` returned from a call to `getReader`, the allowed content length is automatically taken into account.

You can also set the `inputStreamLengthCheck` parameter to `true` in the `contexts.properties` file to prevent this problem.

bookstore
  examples directory 29

C

cache_dir
  optional parameter to NSServletEarlyInit 56
cache directories 24
CatchSignals
  optional parameter to NSServletLateInit 56
CGI variable
  returning in a servlet 76
clarifications
  of API 73
ClassCache 24
classpath
  for JDK 23
  for JVM 26
  for servlets 18
  JVM parameter 26
compiler
  JVM parameter 26
compiling
  servlets 10
configuring
  global servlet attributes 16
  individual servlets 18
  JRE/JDK paths 22
  JVM 25, 65
context
  optional parameter to NSServletService 56
contexts 22, 61
contexts.properties 56, 61
cookies method 77

D

debugging
  enabling 26
  JSPs 68
  servlets remotely 67
deletePool
  parameter for JdbcSessionManager 51
deleting
  version files 24
directives
   for enabling servlets  55
directories
   for servlets  16
doGet method  31, 32

E
enable class GC
   JVM parameter  26
enable debug
   JVM parameter  26
enabling
   JdbcSessionManager  51
   JDK or JRE  22
   JSP  14
   MMapSessionManager  48
   servlets  15
   session managers  45
   SimpleSessionManager  46
examples
   form that invokes JSP  38
   JSP  35
   JSP accessing beans  37
   location in the build  29
   servlets  30
   servlet that parses input parameters  32
   shipped in the build  29
   simple servlet  31
   virtual servlet path  20

F
file extensions
   .class  17
   .jsp  14, 57
forms
   example of invoking JSP  38
   forward  77

G
garbage collection
   enabling  26
